Connecting Login to Home page

The current dilemma is that I'm looking into how to connect the Login page and home page, so once we set up the database and a user successfully log in, they'll be redirected there. However, it's not just an easy export function and import function as React Vite and React Native don't operate the same.

Login:

- Currently using React Native and JavaScript

Current Frontend (Homepage and other pages)

- Currently using React Vite

Possible approach without changing anything

- This would require a shared backend with a mutual API in use. The login screen would send credentials to my auth endpoint, get back a token (JWT or session), and store it. The Vite app uses the same endpoint and token format.

My only problem with this approach is that since it's more than one person working on this project there'll be cases when the connection might fail since everyone's set up isn't the same.

Possible approach that includes changes

- Since the login screen is pretty much done, I could just convert the frontend that I coded in React Vite into React Native so that it'll be compatible. To me this choice makes more sense since I didn't complete that much. Plus, I can utilize Claude to generate some blank pages to get the connection working first and then try to carry over what I did in React Vite.
